

## Screenshots:

This error keeps appearing so I wasn't able to print the functions and the collision rate.

## Which is better?

I believe that linear probing is better because it is easier and faster to search for an element in an array rather than follow pointers in a linked list.

## Hash Function:

In my hash function I added all the letters in each of the employees' names and then divided the total by 10 and used the remainder as the index (modulo operation). I used this hash function because I believe it is random and distributes the employees across the table.

## References:

I used your code for the linked list hash table as reference
